Abstract

Introduction: Non-neurogenic dysfunctional voiding (NDV) accounts for a significant portion of pediatric urology outpatient clinic visits. Biofeedback (BF) is a promising, non-invasive modality for treating children with DV and daytime wetting. Our objective was to investigate BF’s efficacy as a single first-line treatment for children with NDV and diurnal enuresis.

Methods: A retrospective cohort study was conducted with a total of 61 consecutive patient records from January 2009 to March 2016. All children with NDV who had BF as first-line treatment were included. Full urological histories, physical examinations, dysfunctional voiding symptom score (DVSS), urine analysis, ultrasound (US), and uroflowmetry (UFM) and electromyogram (EMG) were performed and recorded for all patients before and after finishing the last BF cycle. The patient’s satisfaction scale was also obtained.

Results: The mean age was 10±2.6 years. Most patients (80.3%) were females. The presenting symptoms were diurnal enuresis, urinary tract infections and voiding discomfort in 52 (85.2%), 16 (26.2%), and 38 (62.3%) patients, respectively. Six months after the last BF cycle, there was a statistically significant objective improvement in US and UFM+EMG findings, with the disappearance of EMG signals in 40 of 61 (65.5%) patients. There was also a significant subjective symptomatic improvement, as the mean DVSS had decreased from 14 to 7.9 (p=0.003). Forty-seven patients (77%) were satisfied, while only eight (13.1%) were not.

Conclusions: BF is considered a potentially effective, single first-line treatment for children with DV and diurnal enuresis, to help these children to be more aware of their normal voiding cycle, and to help them relax their pelvic floor muscles voluntarily during voiding.5,6 The use of computer-based audio and visual games that are used to maintain the interest of a child, in conjunction with a BF therapist who acts as a coach and gives hints on how to improve the child’s performance, make it an attractive treatment option for children with DV.5,6

BF by itself can’t cure NDV; BF depends mainly on the children and their families’ motivation and their dedication to the program, in addition to the standard behavioural therapy. The children must commit themselves to practice pelvic floor muscles exercises daily, and they must accept their responsibility for maintaining their own health.

In the literature, the studies that address using BF as the first, single-line treatment for NDV are scare. Our objective was to investigate BF’s efficacy as a single first-line treatment for NDV children with diurnal enuresis in conjunction with the standard behavioural modifications.

Methods

This is a retrospective cohort study, in which data were obtained between January 2009 and March 2016 in our institute from a prospectively maintained database. This study was approved by our institutional research ethics board. All children >5 years of age with abnormal voiding patterns or diurnal enuresis with NDV, as documented by electromyogram (EMG) signals in uroflowmetry (UFM)+EMG, were enrolled in the study. Patients with the following criteria were excluded from the study: 1) those with neurological

Introduction

Pediatric dysfunction voiding (DV) accounts for a significant portion of outpatient pediatric urologist clinics visits. DV can have either a neurogenic or non-neurogenic etiology.1,2 A non-neuropathic dysfunctional voiding (NDV) child could present with recurrent urinary tract infections (UTIs), diurnal enuresis, and/or voiding discomfort.3 Classical NDV management starts with behavioural therapy. If behavioural therapy fails, the other treatment options could be one or more of: 1) anticholinergics; 2) alpha-adrenergic blockers; 3) intravesicular botulinum toxin injections; and/or 4) biofeedback (BF).4

BF is a non-invasive, promising modality for treatment of children with DV and daytime enuresis, to help these children to be more aware of their normal voiding cycle, and to help them relax their pelvic floor muscles voluntarily during voiding.5,6 The use of computer-based audio and visual games that are used to maintain the interest of a child, in conjunction with a BF therapist who acts as a coach and gives hints on how to improve the child’s performance, make it an attractive treatment option for children with DV.5,6

BF by itself can’t cure NDV; BF depends mainly on the children and their families’ motivation and their dedication to the program, in addition to the standard behavioural therapy. The children must commit themselves to practice pelvic floor muscles exercises daily, and they must accept their responsibility for maintaining their own health.

In the literature, the studies that address using BF as the first, single-line treatment for NDV are scare. Our objective was to investigate BF’s efficacy as a single first-line treatment for NDV children with diurnal enuresis in conjunction with the standard behavioural modifications.
abnormality; 2) patients who had undergone surgical intervention or received medical treatment for management of their NDV; and 3) patients unable to follow the biofeedback protocol because of his/her low mental status or whose place of residence was too far and could not get to the BF sessions.

All patients were exposed to thorough evaluation before starting the BF sessions (full urological history and physical examination). A subjective assessment of the DV symptoms was conducted by self-assessment dysfunctional voiding symptom score (DVSS). Urine analyses (UA), ultrasound (US), and UFM+EMG with assessment of post-voiding residual (PVR) were conducted for all patients before starting the BF cycle.

Each BF cycle was composed of six sessions with one week between sessions. The initial assessment and BF protocol planning were conducted based on the first session. After finishing each session, the BF therapist instructed the child and his/her parents about home pelvic floor muscle exercises, timed voiding, voiding position, self-cleaning, and dietary control. Their home compliance was recorded. At the end of the BF cycle, each patient was reassessed subjectively by DVSS and patients’ satisfaction scale forms that had been filled out by the child or his/her family. Six months later all of the patients were reassessed objectively by UA, US, and UFM+EMG with PVR assessment.

BF cycles were repeated once or twice if there was unsatisfactory objective improvement in the patient’s clinical condition and if the patient's family was motivated to do more cycles in order to improve their child's performance.

Data with different variables were illustrated by simple frequency distribution, t-test, and paired t-test, which were used to compare quantitative data. A Z-score test was also used for comparing percentages in both groups (such as before and after BF). The level of significance was set at 95%.

Results

The study included a total of 61 patients with average age of 10±2.6 years (range 5–7). Most of our patients were female (49, 80.3%). The presenting symptoms included daytime wetting (52, 85.2%), recurrent UTIs (16, 26.2%), and/or voiding discomfort or straining during voiding (38, 62.3%) (Fig. 1).

All patients had hyperactive pelvic floor muscles, as seen on the EMGs. It is also worth mentioning that 24 (39.3%) patients received one BF cycle, 31 (50.8%) patients received two cycles, and only six (9.8%) patients received three BF cycles. Only 30 patients were compliant with home instructions and pelvic floor muscles exercises. Subjective and objective parameters before and after BF cycles are illustrated in Tables 1 and 2.

There was a statistically significant symptomatic improvement in diurnal enuresis, UTIs, and voiding discomfort. The mean DVSS decreased significantly from 14±4.9 to 7.9±5 (p=0.003), as shown in Table 1.

After assessing the objective parameters, including hydronephrosis/renal parameters and PVR, as shown by US, UFM curve shape, and Q-average (Q\text{ave}) in UFM, it was observed that all parameters improved significantly, with disappearance of EMG signals in 40 (65.5%) patients (p=0.000) (Table 2).

When we followed the patients for at least six months, we found 30 (49%) stopped doing the biofeedback and the reported recurrence of symptoms was 47%.

After examining the overall patient satisfaction after BF sessions, it was noted that 47 (77%) patients were satisfied, six (9.8%) were neutral, and eight (13.1%) were not satisfied. In our series, we did not encounter any adverse events related to use of BF or urotherapy.

Discussion

In the literature, BF use, in addition to the standard behavioural modifications in children with NDV, showed variable results. One-third of the children with NDV showed unsatisfactory results if urotherapy was used alone. In the current study, we evaluated BF’s effectiveness as a first-line treatment for NDV in children with diurnal urinary enuresis.

Two systematic reviews were done looking at BF’s effect on daytime wetting in children and they showed contradictory results. Fazeli et al did a systematic review and meta-analysis of randomized controlled trials looking at BF’s effects on NDV and found the overall proportion of cases with resolved

We acknowledge that the retrospective design of our study and the small number of patients are its main limitations. We are working on longer-term, prospective studies in this population.

**Conclusion**

BF is a reliable and feasible first-line treatment modality for children with NDV and diurnal enuresis. Prospective studies on long-term outcomes using this approach are necessary to support our data.
