Abstract

Introduction: Surgical management options for lower urinary tract symptoms/benign prostatic hyperplasia (LUTS/BPH) associated with prostates of small to moderate volume (<80 cc) are numerous; however, for men with enlarged prostates (>80 cc), many of these options are neither safe nor effective. Recently, Aquablation (PROCEPT BioRobotics, Inc., U.S.), a precise ultrasound-guided, robotically executed prostatic ablative procedure, has become available with U.S. Food and Drug Administration approval. Herein, we present three-month safety and efficacy data from the cohort of Canadian men included in the WATER II trial.

Methods: WATER II is a prospective clinical trial of the Aquablation system for the treatment of BPH in men with prostate volumes between 80 and 150 cc. Only patients from Canada were included for this analysis. At baseline, subjects completed International Prostate Symptom Score (IPSS), as well as several validated questionnaires, uroflowmetry and post-void residual volume measurements, and underwent standard laboratory blood assessment. These were repeated at one and three months post-Aquablation.

Results: A total of 19 subjects who met inclusion and exclusion criteria were enrolled at three Canadian academic sites. Mean pre-, one-month, and three-month post-treatment IPSS scores were 21.2±5.5, 9.9±6.9 (p<0.0001), and 5.0±4.5 (p<0.0001), respectively. Mean pre-, one-month, and three-month post-treatment maximum urinary flow rates (Qmax) were 6.6±3.1 ml/s, 19.5±6.1 ml/s (p<0.0001), and 23.1±9.2 ml/s (p<0.0001), respectively. The Clavien-Dindo grade 2 or higher event rate at three months was 31.6% (six events).

Conclusions: In this short-term, three-month analysis of Canadian men, Aquablation appears to provide a strong surgical alternative in patients with LUTS/BPH due to larger prostate volumes, with impressive functional outcomes, relatively short operative time and length of hospital stay, and acceptable complication and low transfusion rates.

Introduction

Lower urinary tract symptoms secondary (LUTS) to benign prostatic hyperplasia (BPH) increases significantly with age.1 The occurrence of moderate-to-severe LUTS occurs in about one-quarter of men in their 50s, one-third of men in their 60s, and about half of all men 80 years or older.2 While LUTS/BPH is often not life-threatening, it can have a significant impact on quality of life (QoL) and, when left untreated, may lead to serious complications, such as infection, calculus formation, bleeding, urinary retention, and deterioration of renal function.3 Although medical therapy (alpha1-selective adrenergic receptor antagonists and in-combination with 5-alpha-reductase inhibitors for larger prostates) has remained the cornerstone of BPH therapy, undesired side-effect profiles, lifetime drug commitment, and progression of LUTS must be considered during patient counselling.3

Surgical management options for LUTS/BPH associated with prostates of small to moderate volume (<80 cc) are numerous and include traditional transurethral resection and laser endoscopic techniques (vaporization/enucleation), with varying success rates.4,5 However, for men with significantly enlarged prostates (>80 cc), many of these options are neither safe nor effective and not recommended as per Canadian Urological Association (CUA), American Urological Association (AUA), and European Association of Urology (EAU) guidelines.4,6 Although not commonly performed in the modern era with access to less invasive alternatives, open simple prostatectomy (OSP) is an appropriate and effective treatment alternative for large prostates. OSP is the most invasive surgical method, requiring not only abdominal wall access, but longer hospitalization and catheterization, with reported transfusion rates from 7–24%.7–10 Long-term complications include transient urinary incontinence (8–10%), as well as bladder neck contracture and urethral stricture (5–6%).4,7,8 Moreover, GreenLight XPS (Boston Scientific, Marlborough, MA, U.S.) photoselective vaporization (PVP) has been well-studied as an alternative in large prostates, particularly for anticoagulated men;11 however, risks of higher retreatment...
rates and need for conversion to transurethral resection due to intraoperative bleeding have been observed.\textsuperscript{11,12} In addition, unless ejaculatory duct preservation is performed for PVP, most, if not all patients will have retrograde ejaculation regardless of the modality that is used.

Finally, holmium enucleation of the prostate (HoLEP) has been extensively studied in large prostates, demonstrating significant and durable improvements in all voiding parameters, completed International Prostate Symptom Score (IPSS), and prostate-specific antigen (PSA) reduction, and can be used to treat men on anticoagulation and those with bleeding dyscrasia.\textsuperscript{13-15} There is a low reoperation rate (approximately 4\% for recurrent LUTS) with long-term followup (up to 7–8 years).\textsuperscript{16} Unfortunately, despite compelling data, HoLEP has not been widely adopted, largely due to a steep learning curve (estimated >20–50 cases)\textsuperscript{16} often requiring fellowship training. Operating time, difficulty of the enucleation, and need for intravesical morcellation seem the most important hurdles for a beginner.\textsuperscript{17}

More recently, Aquablation (PROCEPT BioRobotics, Inc., U.S.), a robotically executed, surgeon-guided, ultrasound imaging-aided, waterjet treatment has become available, with U.S. Food and Drug Administration approval in December 2017 as an option for the management of LUTS/BPH.\textsuperscript{18} In short, Aquablation therapy is the only treatment for BPH that combines the three key elements to remove prostate tissue safely, quickly, and precisely, namely 1) real-time, multidimensional imaging for improved decision-making and treatment planning; 2) accuracy of an autonomous robot for precise treatment execution according to the surgeon’s plan; and 3) power of a heat-free waterjet, which eliminates the possibility of complications arising from thermal injury. In a randomized, double-blinded trial of Aquablation vs. transurethral resection of prostate (TURP) in men with 30–80 cc prostates (WATER trial), Aquablation demonstrated non-inferior symptom relief as compared to TURP, but with considerable reduction in resection time and a lower risk of sexual dysfunction.\textsuperscript{19} Notably, Aquablation was associated with a superior symptom relief benefit in a subgroup of larger (50–80 cc) prostates. Such results thus served as the impetus for the WATER II trial, a single-arm, prospective, multicentre, international clinical trial of Aquablation for the surgical treatment of LUTS/BPH associated with large-prostate volumes (80–150 cc). Data demonstrating one-month feasibility and safety were recently published.\textsuperscript{20} Herein, we present longer three-month safety and efficacy data from the cohort of Canadian men included in the WATER II trial.

Methods

Study design

WATER II (NCT03123250) is a prospective, multicentre, international clinical trial of the Aquablation system for the treatment of BPH in men 45–80 years of age with a transrectal ultrasound-measured prostate volume between 80 and 150 cc.\textsuperscript{20} Only patients from Canada were included for this analysis. Inclusion criteria for this study were baseline IPSS $\geq 12$, a maximum urinary flow rate (Qmax) $<15$ mL/s, a serum creatinine $<2$ mg/dL, a history of failed medical therapy, and mental capacity to participate in the study. Exclusion criteria were body mass index $\geq 42$ kg/m$^2$, history of prostate or bladder cancer, clinically significant bladder calculus or bladder diverticulum, cystitis, previous urinary tract surgery, urinary catheter use daily for 90 or more consecutive days, chronic pelvic pain, urethral stricture, mental status, or bladder neck contracture, use of anticholinergic agents specifically for bladder problems, and any other conditions that could prevent adequate followup. Patients were not excluded for prior prostate surgery or if in retention unless the catheter was in place for more than 90 days. The study was performed with Institutional Review Board approval from each participating institution and all participants provided informed consent.

Study parameters

At baseline, subjects completed IPSS,\textsuperscript{21} as well as several validated questionnaires (Incontinence Severity Index, Pain Intensity Scale, International Index of Erectile Function [IIEF-5],\textsuperscript{22} the Male Sexual Health Questionnaire [MSHQ-EjD]\textsuperscript{23}, uroflowmetry and PVR volume measurements, and underwent standard laboratory blood assessment. Questionnaires, uroflowmetry, PVR, and laboratory tests were also required at postoperative visits at one and three months. Adverse events were recorded and rated by the clinical events committee as possibly, probably, or definitely related to the study procedure classified as Clavien-Dindo (CD)\textsuperscript{24} grades through a minimum of three months post-treatment.

Aquablation technique and postoperative care

Aquablation was performed using the AquaBeam System (PROCEPT BioRobotics, Redwood City, CA, U.S.), as described previously.\textsuperscript{19} Following the Aquablation treatment, the bladder was thoroughly irrigated to remove residual prostate tissue and blood clots. Hemostasis was achieved using tissue tamponade with a low-pressure Foley balloon catheter, which was inflated with 40–80 cc of water. In addition, a tension-free traction device was used to maintain...
traction for 4–20 hours post-procedure. If bleeding was a concern, the balloon was inflated within the prostatic fossa with adequate traction using transrectal ultrasound (TRUS) guidance prior to commencing irrigation. Unique to the procedures performed in Montreal, after the steps described above, the bladder was maintained under pressure and the saline bag was attached as quickly as possible to maintain bladder pressure while the outflow was plugged. The saline was stopped once the bladder was full, establishing hydrostatic pressure against the bladder neck. Patients then went to recovery without continuous bladder irrigation (CBI).

At approximately 45 minutes, the surgeon checked on the patient, unplugged the outflow, and started CBI. Manual irrigation was performed if required. During the next 1–4 hours, nurses aggressively titrated down the CBI flow.

Statistical analysis

A standard statistical approach was used for analysis that used the Student’s t-test for continuous variables and Fisher’s test for ordinal/binary variables. All statistical analysis was performed using R.25 P value ≤0.05 was considered statistically significant. Additional analysis, such as a Canada-only cohort, was allowed per protocol.

Results

Procedural outcomes

Of 23 screened patients, 19 subjects (19% of subjects enrolled in Water II) who met inclusion and exclusion criteria were enrolled at three Canadian academic sites between November and December 2017. Of those, 18 subjects completed the three-month follow-up visit. All three sites had no prior Aquablation experience. Baseline characteristics are summarized in Table 1. Mean age was 66.0±6.9 years and mean baseline IPSS score was 21.2±5.5 points. Study procedures were performed under spinal anesthesia. Prostate volume ranged from 80–148 cc (consistent with study eligibility criteria) with a mean volume of 105.6±16.6 cc. A middle lobe was present in 74% of cases, with an average protrusion distance of 1.5±0.5 cm.

Mean operative time, defined as handpiece placement until final urinary catheter placement, was 33.7±7.8 minutes. The mean Aquablation resection time was 9.0±2.4 minutes. The number of men requiring a single pass, two passes, and more than two passes during resection were 26%, 68%, and 5%, respectively. None of the patients in this cohort required post-Aquablation cautery for hemostasis. The average length of stay following the procedure was 1.3±0.8 days. At the Montreal site, two patients went home the same day as surgery. The average duration to final catheter removal was 2.1±1.5 days. Hemoglobin levels decreased from a mean of 14.6±1.5 g/dL at baseline to 12.2±1.8 g/dL postoperatively (p<0.0001).

Clinical endpoints

Mean pre-, one-month, and three-month post-treatment IPSS scores were 21.2±5.5, 9.9±6.9 (p<0.0001), and 5.0±4.5 (p<0.0001), respectively. Mean pre-, one-month, and three-month post-treatment IPSS QoL scores were 4.3±1.2, 2.1±1.9

**IIEF: International Index of Erectile Function; IPSS: International Prostate Symptom Score; MSHQ-EjD: Male Sexual Health Questionnaire – ejaculatory dysfunction; QoL: quality of life; SD: standard deviation; TRUS: transrectal ultrasound.

Fig. 1. One- and three-month functional outcomes following Aquablation in 19 men with lower urinary tract symptoms/benign prostatic hyperplasia and large prostates. (A) International Prostate Symptom Score (IPSS); (B) IPSS quality of life (QoL); (C) maximum urinary flow rate (Qmax); (D) post-void residual (PVR). *Statistical significance compared to baseline. **Statistical significance compared to one month. CI: confidence interval.
compared to open prostatectomy, HoLEP, and PVP. The rate of antegrade ejaculation preservation is very low unless ejaculatory duct-sparing is performed. If this is not done, the IPSS drop is from 23 to 6 and Qmax increases from 6 to 16 ml/s (p<0.0001), respectively. Mean pre-, one-month, and three-month post-treatment Qmax were 6.6±3.1 ml/s, 19.5±6.1 ml/s (p<0.0001), and 23.1±9.2 ml/s (p<0.0001), respectively. Mean pre-, one-month, and three-month post-treatment PVRs were 174.9±142.9 cc, 48.9 ±42.2 cc (p<0.0001), and 77.7±73.6 cc (p<0.0001), respectively. Outcomes are summarized in Fig. 1. Finally, at three months, average prostate volume decreased from 106 cc to 59 cc.

Treatment-related adverse events

The CD grade 2 or higher event rate at three months was 31.6% (six events). This was comprised of five voiding issue events (frequency, urgency, or dysuria) and one urinary tract infection. Two of these cases were CD 3a, which were cystoscopies for urinary frequency and dysuria.

There were no reports of blood transfusions. The CD grade 1 persistent events consisted of ejaculatory dysfunction (32%). There were no reported cases of incontinence (0%) or erectile dysfunction (0%).

Discussion

Our findings demonstrate that Aquablation of the prostate is a practical and viable option for the treatment of large-sized prostate glands (80–150 cc). The Canadian subset of patients within this prospective multicentre Aquablation WATER II trial provides several noteworthy findings. First, 19 of 19 (100%) cases were successfully completed for prostates >100 cc on average. No case was aborted, no case required cautery for hemostasis, and no secondary procedures were necessary. Second, total operative time and total resection time were 33.7 minutes and nine minutes, respectively, on average for men with a mean prostate volume of 106 cc. Comparatively, the average time to perform a 100 cc prostate done via open prostatectomy is 95 minutes,26 via HoLEP is 91 minutes,27 and via PVP is 93 minutes.11 It should also be noted that this was the first experience for each institution and each surgeon with the Aquablation system and therefore, the total operative time should get shorter with greater surgical experience and proficiency with technique and instrumentation.

Third, IPSS and Qmax at one and three months postoperatively improved significantly and incrementally from preoperative baseline. These clinical improvements (IPSS reduced from 21 to 5 and Qmax increased from 6.6 to 23 ml/s) are comparable to those found with HoLEP (IPSS drop from 20 to 5.3 and Qmax increases from 8.4 to 22.7 ml/s30) and PVP (IPSS drop from 23 to 6 and Qmax increases from 6 to 16 ml/s31). Additionally, 2/3 of patients maintained antegrade ejaculation. Unless ejaculatory duct-sparing is performed, the rate of antegrade ejaculation preservation is very low compared to open prostatectomy, HoLEP, and PVP.

Fourth, and most importantly, complications associated with this procedure were uncommon and low-grade. Additionally, no patient has required further surgical treatment and no transfusions have been reported. In comparison with the larger study population, no patient in this cohort required a blood transfusion. This is most likely due to the postoperative procedure care, as highlighted in the methods section of this manuscript. This is particularly important when comparing Aquablation to OSP, for which transfusion rates have been found to be 7–24%.9,10

Finally, length of stay following the Aquablation procedure was 1.3±0.8 days, which is very comparable to HoLEP (1–1.3 days15,29) and PVP (1–2 days10) and much shorter than OSP (3–7 days9,31). In addition, at the Montreal site, two patients were sent home the same day of the procedure with catheter removal 24–48 hours later. Further, experience with the Aquablation system and postoperative optimization should lead to more patients being discharged in a shorter amount of time and it is plausible that this procedure could become an outpatient procedure.

Despite its merits, this study is not devoid of limitations. One of the limitations is that this study was a non-randomized, single-arm study. The impact of the study would have been greater if the study compared Aquablation to HoLEP, PVP, or open prostatectomy. In addition, the cohort was small and surgeon’s experience was limited. Finally, and most importantly, the followup of this cohort is only three months. Longer-term followup is necessary to demonstrate the durability of the treatment outcomes.

The landscape of BPH surgical treatment has changed significantly over the past decade. It is a very exciting time, with numerous surgical options. Smaller prostate glands (<50 cc) can be treated by almost any modality and newer, office-based modalities have begun to dominate this patient subpopulation. Medium-sized prostate glands (50–80 cc) require more innovative technique, such as HoLEP or PVP, as well as possible office-based modalities. Large-sized glands (>80 cc) are the most challenging and are currently managed with OSP and HoLEP and, if the gland is not too large (<100 cc), TURP or PVP are also options. Unfortunately, HoLEP is an ultraspecialized technique that only a handful of urologists can perform in Canada. This translates into long wait times for surgery or more OSPs being performed. Aquablation is now an option for this patient subpopulation, with both FDA and Health Canada approval; the updated CUA BPH guidelines have also included Aquablation as an option for surgical management of LUTS due to bladder outlet obstruction.4

In Canada, with a uniquely socialized medical system and budget-dependent, volume-limited structure to limit costs, operating room time is at a premium and consequently must be used as efficiently as possible. Therefore, an effective treatment that cuts operating room time by more than
50% should be considered a major advantage. Moreover, a treatment that is ultrasound-guided and robotically executed under precise and reproducible parameters should be considered standard of care. In the age of healthcare reform, Canadian surgical treatment of BPH, with >20 000 TURPs performed annually, should be scrutinized to maximize outcomes and minimize both individual treatment cost, as well as patient lifetime BPH medical/surgical costs (annual dual therapy cost of $1000/year coupled with repeat TURP surgical rate of 5–10%).

Conclusion

In this short-term, three-month analysis of Canadian men, Aquablation appears to provide a strong surgical alternative in patients with LUTS/BPH due to larger prostate volumes, with impressive functional outcomes, relatively short operative time and length of hospital stay, and acceptable complication and low transfusion rates. The recently developed CUA guidelines lists Aquablation as an alternative and effective surgical option for patients suffering from LUTS due to moderate-/large-sized prostate volumes. This precise ultrasound-guided, robotically executed prostatic ablative procedure provides excellent clinical outcomes with minimal complications. Longer-term followup is ongoing to confirm these results.
